1. INTRODUCTION

In [FL04], it is shown that the $RO(\mathbb{Z}/p)$ -graded homology of a \mathbb{Z}/p -space built of only even dimensional cells is free as a module over the homology of a point, regardless of which Mackey functor is chosen for coefficients. The goal of this paper is to establish the following related result.

Theorem. If X is a connected, locally finite, finite dimensional $\text{Rep}(\mathbb{Z}/2)$ -complex, then $H^{*,*}(X; \mathbb{Z}/2)$ is free as a $H^{*,*}(pt; \mathbb{Z}/2)$ -module.

The projective spaces and Grassmann manifolds associated to representations of $\mathbb{Z}/2$ are examples of such $\text{Rep}(\mathbb{Z}/2)$ -complexes. In these particular cases, the free generators of the cohomology modules are in bijective correspondence with the Schubert cells. The bidegrees of these cohomology generators generally remains unknown, much like in [FL04].

Section 2 provides some of the background required for the rest of the paper. Most of this information can be found in [May96] and [FL04] but is reproduced here for convenience. Section 3 holds the main freeness theorem. As applications of the freeness theorem, section 4 contains computations of the $RO(\mathbb{Z}/2)$ -graded cohomology of some Grassmann manifolds, exhibiting some techniques for calculating the cohomology of $\text{Rep}(\mathbb{Z}/2)$ -complexes. The importance of such calculations lies in their potential applications toward understanding $RO(\mathbb{Z}/2)$ -graded equivariant characteristic classes.

The work in this paper was originally part of the author's dissertation while at the University of Oregon.

The author is indebted to Dan Dugger for his guidance and innumerable helpful conversations.

Date: July 8, 2009.

2. PRELIMINARIES

This section contains some of the basic machinery and notations that will be used throughout the paper. In this section, G can be any finite group unless otherwise specified.

Given a G -representation V , let $D(V)$ and $S(V)$ denote the unit disk and unit sphere, respectively, in V with action induced by that on V . A **Rep(G)-complex** is a G -space X with a filtration $X^{(n)}$ where $X^{(0)}$ is a disjoint union of G -orbits and $X^{(n)}$ is obtained from $X^{(n-1)}$ by attaching cells of the form $D(V_\alpha)$ along maps $f_\alpha: S(V_\alpha) \rightarrow X^{(n-1)}$ where V_α is an n -dimensional real representation of G . The space $X^{(n)}$ is referred to as the **n -skeleton** of X , and the filtration is referred to as a **cell structure**.

For the definition of a Mackey functor for general groups, see [May96]. When $G = \mathbb{Z}/2$, the data of a Mackey functor are encoded in a diagram of abelian groups like the one below.

$$\begin{array}{ccc} & \nearrow t^* & \\ M(\mathbb{Z}/2) & \xrightleftharpoons{i_*} & M(e) \\ & \searrow i^* & \end{array}$$

The maps must satisfy the following four conditions.

- (1) $(t^*)^2 = id$
- (2) $t^*i^* = i^*$
- (3) $i_*(t^*)^{-1} = i_*$
- (4) $i^*i_* = id + t^*$

According to [May96], each Mackey functor M uniquely determines an $RO(G)$ -graded cohomology theory $H_G^*(-; M)$ characterized by

- (1) $H_G^n(G/H; M) = \begin{cases} M(G/H) & \text{if } n = 0 \\ 0 & \text{otherwise} \end{cases}$
- (2) The map $H_G^0(G/K; M) \rightarrow H_G^0(G/H; M)$ induced by $i: G/H \rightarrow G/K$ is the transfer map i^* in the Mackey functor.

If the Mackey functor M is a Green functor (i.e. a ring object in the category of Mackey functors), then $H_G^*(X; M)$ is an algebra over $H_G^*(pt; M)$.

A p -dimensional real $\mathbb{Z}/2$ -representation V decomposes as $V \cong (\mathbb{R}^{1,0})^{p-q} \oplus (\mathbb{R}^{1,1})^q = \mathbb{R}^{p,q}$ where $\mathbb{R}^{1,0}$ is the trivial representation and $\mathbb{R}^{1,1}$ is the nontrivial 1-dimensional representation. When $V \cong \mathbb{R}^{p,q}$, we write $H_{\mathbb{Z}/2}^V(X; M) = H^{p,q}(X; M)$ for the V^{th} graded component of the $RO(\mathbb{Z}/2)$ -graded equivariant cohomology of X with coefficients in a Mackey functor M .

In this paper, G will typically be $\mathbb{Z}/2$ and the Mackey functor will almost always be constant $M = \underline{\mathbb{Z}/2}$ which has the following diagram.

$$\begin{array}{ccc} & \nearrow id & \\ \mathbb{Z}/2 & \xrightleftharpoons[0]{id} & \mathbb{Z}/2 \\ & \searrow id & \end{array}$$

Even with these constant coefficients, the $RO(\mathbb{Z}/2)$ -graded cohomology of a point is complicated to describe. As a bigraded $\mathbb{Z}/2$ -vectorspace, $H^{*,*}(pt; \underline{\mathbb{Z}/2}) \cong$

$\mathbb{Z}/2[\tau, \rho] \oplus \text{Span}_{\mathbb{Z}/2} \left\{ \frac{\theta}{\tau^i \rho^j} \right\}_{i,j \geq 0}$, where τ , ρ , and θ have bidegrees $(0, 1)$, $(1, 1)$, and $(0, -2)$, respectively. A plot of $H^{*,*}(pt; \mathbb{Z}/2)$ in the pq -plane is given in Figure 1.

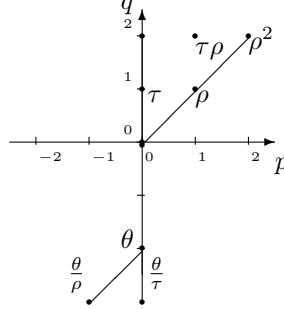

FIGURE 1. $H^{*,*}(pt; \mathbb{Z}/2)$

The bigraded algebra structure is implicit in the notation. Every lattice point in the picture that is inside the indicated cones represents a copy of the group $\mathbb{Z}/2$. The **top cone** is a polynomial algebra on the nonzero elements $\rho \in H^{1,1}(pt; \mathbb{Z}/2)$ and $\tau \in H^{0,1}(pt; \mathbb{Z}/2)$. The nonzero element $\theta \in H^{0,-2}(pt; \mathbb{Z}/2)$ in the **bottom cone** is infinitely divisible by both ρ and τ . The cohomology of $\mathbb{Z}/2$ is easier to describe: $H^{*,*}(\mathbb{Z}/2; \mathbb{Z}/2) = \mathbb{Z}/2[t, t^{-1}]$ where $t \in H^{0,1}(\mathbb{Z}/2; \mathbb{Z}/2)$. Details can be found in [Dug05] and [Car99].

A useful tool is the following exact sequence of [AM78].

Lemma 2.1 (Forgetful Long Exact Sequence). Let X be a based $\mathbb{Z}/2$ -space. Then for every q there is a long exact sequence

$$\cdots \longrightarrow H^{p,q}(X) \xrightarrow{\cdot\rho} H^{p+1,q+1}(X) \xrightarrow{\psi} H_{sing}^{p+1}(X) \xrightarrow{\delta} H^{p+1,q}(X) \rightarrow \cdots$$

The map $\cdot\rho$ is multiplication by $\rho \in H^{1,1}(pt; \mathbb{Z}/2)$ and ψ is the forgetful map to singular cohomology with $\mathbb{Z}/2$ coefficients. This forgetful long exact sequence is unique to the $\mathbb{Z}/2$ -equivariant setting and is essential to the proof of the main freeness theorem.

3. THE FREENESS THEOREM

Computing the $RO(G)$ -graded cohomology of a G -space X is typically quite a difficult task. However, if X has a filtration $X^{(0)} \subseteq X^{(1)} \subseteq \cdots$, then we can take advantage of the long exact sequences in cohomology arising from the cofiber sequences $X^{(n)} \subseteq X^{(n+1)} \rightarrow X^{(n+1)}/X^{(n)}$. These long exact sequences paste together as an exact couple in the usual way, giving rise to a spectral sequence associated to the filtration.

If X is a G -CW complex or a $\text{Rep}(G)$ -complex, then X has a natural filtration coming from the cell structure. In either case, if X is connected, the quotient spaces $X^{(n+1)}/X^{(n)}$ are wedges of $(n+1)$ -spheres with action determined by the type of cells that were attached. Examples of this sort appear throughout the paper.

For the remainder of the paper, we will only be interested in the case $G = \mathbb{Z}/2$ and always take coefficients to be $\mathbb{Z}/2$. These choices will be implicit in our notation.

Given a filtered $\mathbb{Z}/2$ space X , for each fixed q there is a long exact sequence

$$\cdots H^{*,q}(X^{(n+1)}/X^{(n)}) \rightarrow H^{*,q}(X^{(n+1)}) \rightarrow H^{*,q}(X^{(n)}) \rightarrow H^{*+1,q}(X^{(n+1)}/X^{(n)}) \cdots$$

and so there is one spectral sequence for each integer q . The specifics are given in the following proposition.

Proposition 3.1. *Let X be a filtered $\mathbb{Z}/2$ -space. Then for each $q \in \mathbb{Z}$ there is a spectral sequence with*

$$E_1^{p,n} = H^{p,q}(X^{(n+1)}, X^{(n)})$$

converging to $H^{p,q}(X)$.

The construction of the spectral sequence is completely standard. See, for example, Proposition 5.3 of [McC01].

It is convenient to plot the $RO(\mathbb{Z}/2)$ -graded cohomology in the plane with p along the horizontal axis and q along the vertical axis, and this turns out to be a nice way to view the cellular spectral sequences as well. When doing so, the differentials on each page of the spectral sequence have bidegree $(1, 0)$ in the plane, but reach farther up the filtration on each page. It is important to keep track of at what stage of the filtration each group arises. In practice, this can be done by using different colors for group that arise at different stages of the filtration.

It is often quite difficult to determine the effect of all of the attaching maps in the cell attaching long exact sequences. If X is locally finite, then the cells can be attached one at a time, in order of dimension. This simplicity will make it easier to analyze the differentials in the spectral sequence of the ‘one at a time’ cellular filtration, even when the precise impact of the attaching maps are not a priori known.

Lemma 3.2. Let B be a $\text{Rep}(\mathbb{Z}/2)$ -complex with free cohomology that is built only of cells of dimension strictly less than p . Let X be obtained from B by attaching a single (p, q) -cell and consider the spectral sequence associated to the filtration $B \subseteq X$. Let ν denote the generator of $X/B \cong S^{p,q}$. Then after an appropriate change of basis either all differentials to the top cone of ν are zero, the cell attaching ‘kills’ ν and a free generator in dimension $(p-1, q)$, or all nonzero differentials hit the bottom cone of ν .

Proof. Choose a set $\{\lambda_i\}$ of free generators of $H^{*,*}(B)$. Let $\{\omega_i\}$ denote the set of λ ’s which have nonzero differentials in the cell attaching spectral sequence. Let $A = \langle \omega_i \rangle$, the $H^{*,*}(pt)$ -span of the ω_i ’s.

Suppose first that all nonzero differentials hit the top cone of ν . Then any free generator ω_i having a nonzero differential in the spectral sequence must have bidegree (p_i, q_i) where $p_i = p-1$ and $q_i \geq q$. (For illustrative purposes, the E_1 page of the cellular spectral sequence of an example of this type is pictured in Figure 2. In this example, A is a free $H^{*,*}(pt)$ -module with two generators in bidegree $(p-1, q_i)$ and one generator in bidegree $(p-1, q_j)$.)

Each of the ω_i satisfies $d(\omega_i) = \tau^{n_i} \nu$ for integers n_i . Relabeling if necessary, we can arrange so that the ω_i satisfy $n_1 \leq n_2 \leq \dots$.

A change of basis can be performed on A , after which we may assume $d(\omega_1) = \tau^{n_1} \nu$ and $d(\omega_i) = 0$ for $i > 1$. Indeed, $\{\tau^{n_i-n_1} \omega_1 + \omega_i\}$ is a basis for A and $d(\tau^{n_i-n_1} \omega_1 + \omega_i) = \tau^{n_1} \nu$ if $i = 1$ and is zero otherwise. (In effect, the attaching map can ‘slide’ off of all the ω_i except for the one for which q_i is minimal.)

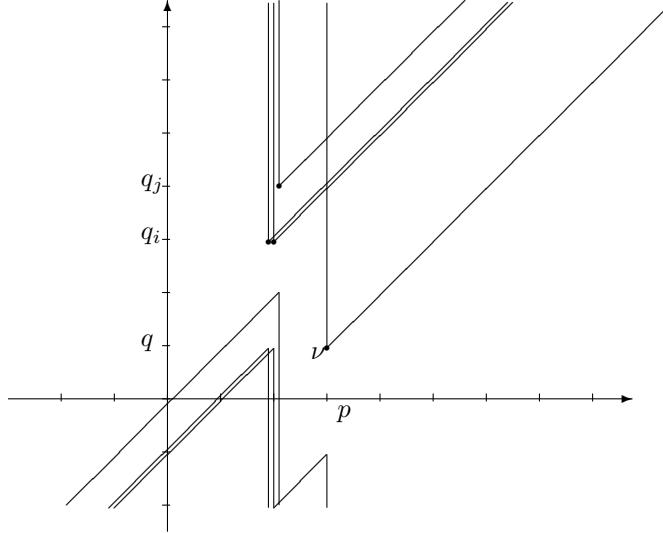

FIGURE 2. An example of the E_1 page of the cellular spectral sequence attaching a single (p, q) -cell to B .

If ω_1 happens to be in dimension $(p - 1, q)$, then the newly attached cell ‘kills’ ω_1 and ν and we are done. Otherwise the nonzero portion of the spectral sequence is illustrated in Figure 3.

After taking cohomology, the spectral sequence collapses, as in Figure 4.

There is a class $\omega_1 \frac{\theta}{\tau^m}$ that, potentially, could satisfy $\rho \cdot \omega_1 \frac{\theta}{\tau^m} = \nu$. However, for degree reasons, $\rho \cdot \omega_1 \frac{\theta}{\tau^{m+1}} = 0$ and since ρ and τ commute, $\rho \cdot \omega_1 \frac{\theta}{\tau^m} = 0$. This means ν determines a nonzero class in $H^{*,*}(X)$ that is not in the image of $\cdot\rho$. If B is based, then X is based, and so, by the forgetful long exact sequence, $\psi(\nu)$ is nonzero in singular cohomology. Then since $\psi(\tau) = 1$ in singular cohomology, $\psi(\tau^n \nu)$ is nonzero for all n . But $\tau^n \nu$ is zero for large enough n . This contradiction implies that there could not have been any nonzero differentials hitting the top cone of ν .

This argument is independent of whether there are any differentials hitting the bottom cone of ν , and so there cannot be any nonzero differentials on the top cone. \square

Theorem 3.3. *Suppose X is a $Rep(\mathbb{Z}/2)$ -complex formed by attaching a single (p, q) -cell to a space B . Suppose also that $\check{H}^{*,*}(B)$ is a free $H^{*,*}(pt)$ -module with a single generator ω . Then $H^{*,*}(X)$ is a free $H^{*,*}(pt)$ -module. In particular, one of the following must hold:*

- (1) $H^{*,*}(X) \cong H^{*,*}(pt)$.
- (2) $H^{*,*}(X) \cong H^{*,*}(B) \oplus \Sigma^\nu H^{*,*}(pt)$, where ν has bidegree (p, q) .
- (3) $H^{*,*}(X)$ is free with two generators a and b .

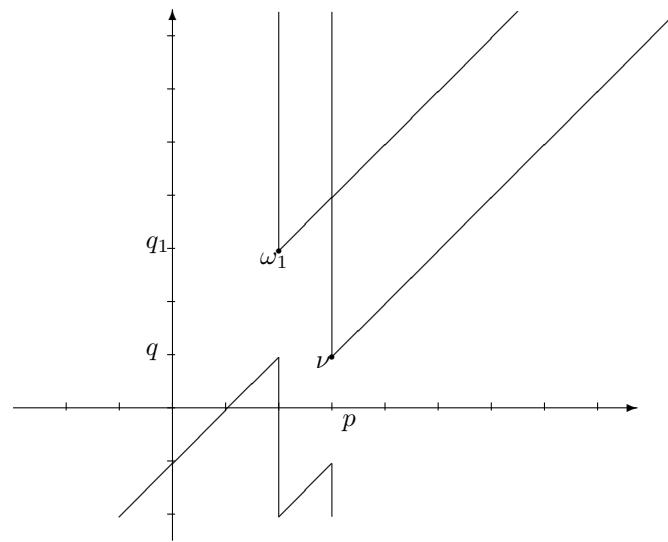

FIGURE 3. The nonzero portion of the cell attaching spectral sequence, after a change of basis.

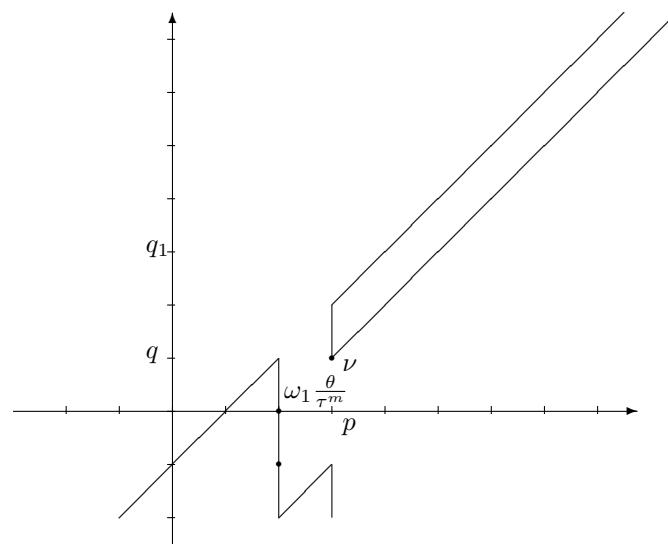

FIGURE 4. The $E_2 = E_\infty$ page of the above spectral sequence.

In (3) above, the bidegrees of the generators a and b are $(p - n - 1, q - n - 1)$ and $(p, q - m - 1)$ where $d(\omega) = \frac{\theta}{\rho^n \tau^m} \nu$ in the spectral sequence for the filtration $B \subseteq X$.

Proof. Under these hypotheses, there is a cofiber sequence of the form $B \xhookrightarrow{i} X \xrightarrow{j} S^{p,q}$. Denote by ν the generator of $H^{*,*}(S^{p,q})$.

If $d(\omega) = \nu$ then (1) holds and $H^{*,*}(X)$ is free. If $d(\omega) = 0$, then (2) holds and again $H^{*,*}(X)$ is free. The remaining case is $d(\omega) \neq 0$. By the previous lemma, $d(\omega)$ is in the bottom cone of ν . That is $d(\omega) = \frac{\theta}{\rho^n \tau^m} \nu$ for some n and m . Recall that ν has dimension (p, q) and so ω has dimension $(p - n - 1, q - n - m - 2)$. The E_1 page of the cellular spectral sequence is given in Figure 5.

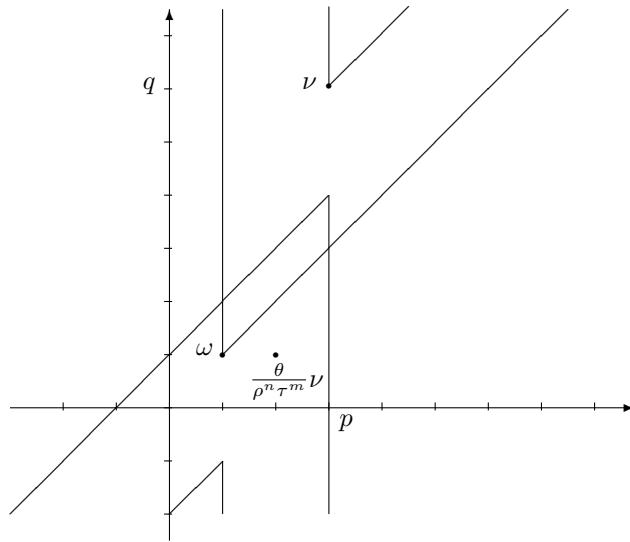

FIGURE 5. The E_1 page of the cellular spectral sequence with a single nonzero differential hitting the bottom cone of an attached (p, q) -cell.

After taking cohomology, the spectral sequence collapses, and what remains is pictured in Figure 6.

Let a be the generator in bidegree $(p - n - 1, q - n - 1)$ and b the generator in dimension $(p, q - m - 1)$. For degree reasons, b is not in the image of $\cdot\rho$ and so determines a nonzero class in singular cohomology. Thus, $\tau^i b$ is nonzero for all i , and so we have that $b_i = \tau^i b$. In particular, $\rho^{n+1} a$ and $\tau^m b$ generate $H^{p,q}(X)$. Consider the portion of the long exact sequence associated to the cofiber sequence $B \xhookrightarrow{i} X \xrightarrow{j} S^{p,q}$ given below:

$$\cdots \longrightarrow H^{p,q}(S^{p,q}) \xrightarrow{j^*} H^{p,q}(X) \xrightarrow{i^*} H^{p,q}(B) \longrightarrow 0$$

Since $i^*(\rho^{n+1} a) = i^*(\tau^m b) = \rho^{n+1} \tau^m \omega$, exactness implies that $j^*(\nu) = \rho^{n+1} a + \tau^m b$. Also j^* is an $H^{*,*}(pt)$ -module homomorphism, and so $j^*(\frac{\theta}{\rho^{n+1}} \nu) = \theta a$ and

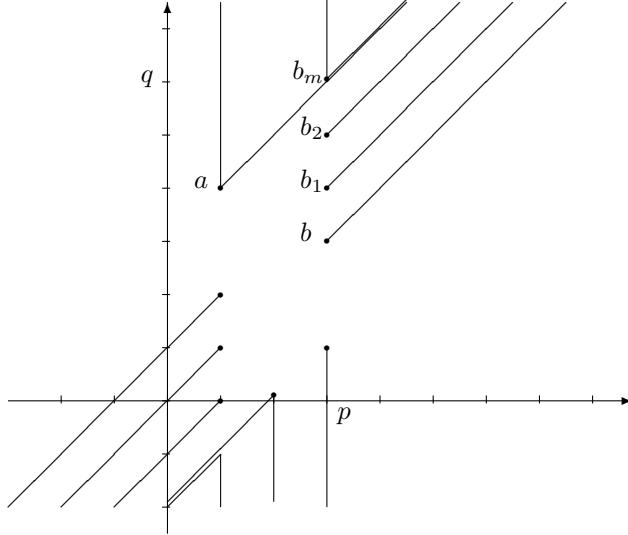

FIGURE 6. The $E_2 = E_\infty$ page of the cellular spectral sequence with a single nonzero differential hitting the bottom cone of an attached (p, q) -cell.

$j^*(\frac{\theta}{\tau^m} \nu) = \theta b$. In particular, we can create a map f from a free module with generators α and β in bidegrees $(p-n-1, q-n-1)$ and $(p, q-m-1)$ respectively to $\tilde{H}^{p,q}(X)$ with $f(\alpha) = a$ and $f(\beta) = b$. This f is an isomorphism. \square

Theorem 3.4 (Freeness Theorem). *If X is a connected, locally finite, finite dimensional $\text{Rep}(\mathbb{Z}/2)$ -complex, then $H^{*,*}(X; \underline{\mathbb{Z}/2})$ is free as a $H^{*,*}(pt; \underline{\mathbb{Z}/2})$ -module.*

Proof. Since X is locally finite, the cells can be attached one at a time. Order the cells $\alpha_1, \alpha_2, \dots$ so that their bidegrees $(p_1, q_1), (p_2, q_2), \dots$ satisfy $p_i \leq p_j$ if $i \leq j$ and $q_i \leq q_j$ if $p_i = p_j$ and $i \leq j$. We can proceed by induction over the spaces in the ‘one-at-a-time’ cell filtration $X^{(0)} \subseteq \dots \subseteq X^{(n)} \subseteq \dots \subseteq X$, with the base case obvious since X is connected.

First, suppose that $H^{*,*}(X^{(n)})$ is a free $H^{*,*}(pt)$ -module, that $X^{(n+1)}$ is obtained by attaching a single (p, q) -cell to $X^{(n)}$, and that $X^{(n)}$ has no p -cells. Denote by ν the free generator of $H^{*,*}(X^{(n+1)}/X^{(n)}) \cong H^{*,*}(S^{p,q})$. Consider the spectral sequence of the filtration $X^{(n)} \subseteq X^{(n+1)}$. An example is pictured below in Figure 7 to aid in the discussion.

As before, a change of basis allows us to focus on a subset $\omega_1, \dots, \omega_n$ of the free generators of $H^{*,*}(X^{(n)})$ whose differentials hit the bottom cone of ν and that satisfy

- (1) $d(\omega_i) \neq 0$ for all i ,
- (2) $|\omega_i| > |\omega_j|$ when $i > j$,
- (3) $|\omega_i^G| > |\omega_j^G|$ when $i > j$,

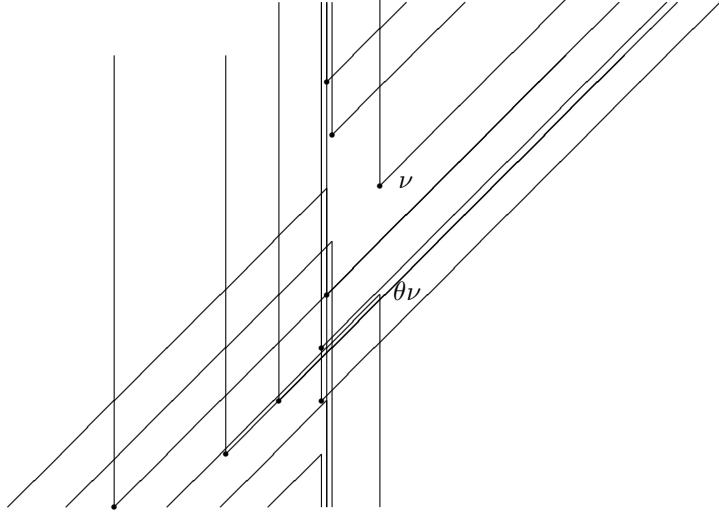

FIGURE 7. The spectral sequence of a filtration for attaching a single (p, q) -cell to a space with free cohomology.

and all other basis elements have zero differentials. (This is similar to what is referred to in [FL04] as a ramp of length n .) Also, we can change the basis again so that there is only one free generator, α , of $H^{*,*}(X^{(n)})$ with a nonzero differential to the top cone of ν . Then, after this change of basis, the nonzero portion of the spectral sequence of the filtration looks like the one in Figure 8

As above, α cannot support a nonzero differential, and we can see that each of the ω_i 's will shift up in degree and ν will shift down. Thus, $H^{*,*}(X^{(n+1)})$ is again free.

Now suppose that $X^{(n+1)}$ is obtained by attaching a (p, q) -cell ν' and that $X^{(n)}$ has a single p -cell ν already. Then by the previous case, the generator for ν was either shifted down, killed off, or was left alone at the previous stage. In any case, because of our choice of ordering of the cells, the generator for ν cannot support a differential to the generator for ν' . Thus, the only nonzero differentials to ν' are from strictly lower dimensional cells. Thus, we are reduced again to the previous case and $H^{*,*}(X^{(n+1)})$ is free. By induction, $H^{*,*}(X)$ is free. \square

4. REAL PROJECTIVE SPACES AND GRASSMANN MANIFOLDS

As before, in this section $G = \mathbb{Z}/2$ exclusively, and the coefficient Mackey will always be $M = \underline{\mathbb{Z}/2}$ and will be suppressed from the notation.

Since each representation $\mathbb{R}^{p,q}$ has a linear $\mathbb{Z}/2$ -action, there is an induced action of $\mathbb{Z}/2$ on $G_n(\mathbb{R}^{p,q})$, the **Grassmann manifold** of n -dimensional linear subspaces of $\mathbb{R}^{p,q}$. These Grassmann manifolds play a central role in the classification of equivariant vector bundles, and so it is important to understand their cohomology. As a special case we have the real projective spaces $\mathbb{P}(\mathbb{R}^{p,q}) = G_1(\mathbb{R}^{p,q})$.

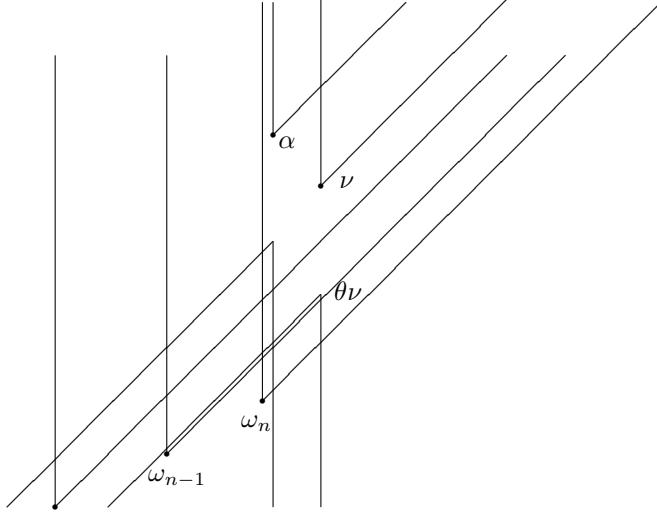

FIGURE 8. The nonzero portion of the above spectral sequence, after a change of basis.

The usual Schubert cell decomposition endows the Grassmann manifolds with a $\text{Rep}(\mathbb{Z}/2)$ -cell structure. However, the number of twists in each cell is dependent upon the flag of subrepresentations of $\mathbb{R}^{p,q}$ that is chosen. A **flag symbol** is a sequence of integers $\varphi = (\varphi_1, \dots, \varphi_q)$ satisfying $1 \leq \varphi_1 < \dots < \varphi_q \leq q$. A flag symbol φ determines a flag of subrepresentations $V_0 = 0 \subset V_1 \subset \dots \subset V_p = \mathbb{R}^{p,q}$ satisfying $V_{\varphi_i}/V_{\varphi_{i-1}} \cong \mathbb{R}^{1,1}$ for all $i = 1, \dots, q$, and all other quotients of consecutive terms are isomorphic to $\mathbb{R}^{1,0}$. For concreteness, we also require that V_i is obtained from V_{i-1} by adjoining a coordinate basis vector. For example, there is a flag in $\mathbb{R}^{5,3}$ determined by the flag symbol $\varphi = (1, 3, 4)$ of the form $\mathbb{R}^{0,0} \subset \mathbb{R}^{1,1} \subset \mathbb{R}^{2,1} \subset \mathbb{R}^{3,2} \subset \mathbb{R}^{4,3} \subset \mathbb{R}^{5,3}$.

A **Schubert symbol** $\sigma = (\sigma_1, \dots, \sigma_n)$ is a sequence of integers such that $1 \leq \sigma_1 < \sigma_2 < \dots < \sigma_n \leq p$. Given a Schubert symbol σ and a flag symbol φ , let $e(\sigma, \varphi)$ be the set of n -planes $\ell \in G_n(\mathbb{R}^{p,q})$ for which $\dim(\ell \cap V_{\sigma_i}) = 1 + \dim(\ell \cap V_{\sigma_{i-1}})$ for all i , where $V_0 \subset \dots \subset V_n$ is the flag determined by φ . Then $e(\sigma, \varphi)$ is the interior of a cell $D(W)$ for some representation W . The dimension of the cell is determined by the Schubert symbol σ just as in nonequivariant topology, but the number of twists depends on both σ and the flag symbol φ .

For example, consider $G_2(\mathbb{R}^{5,3})$, $\sigma = (3, 5)$, and $\varphi = (1, 3, 4)$. Then $e(\sigma, \varphi)$ consists of 2-planes ℓ which have a basis with echelon form given by the matrix below.

$$\begin{pmatrix} - & + & - & - & + \\ * & * & 1 & 0 & 0 \\ * & * & 0 & * & 1 \end{pmatrix}$$

Here, the action of $\mathbb{Z}/2$ on the entries of the matrix, as determined by φ , has been indicated by inserting the appropriate signs above the matrix. After acting, this becomes the following.

$$\begin{pmatrix} - & + & - & - & + \\ -* & * & -1 & 0 & 0 \\ -* & * & 0 & -* & 1 \end{pmatrix}$$

We require the last nonzero entry of each row to be 1, and so we scale the first row by -1 .

$$\begin{pmatrix} - & + & - & - & + \\ * & -* & 1 & 0 & 0 \\ -* & * & 0 & -* & 1 \end{pmatrix}$$

There are five coordinates which can be any real numbers, three of which the $\mathbb{Z}/2$ action of multiplication by -1 , so this is a $(5, 3)$ -cell. Through a similar process, we can obtain a cell structure for $G_n(\mathbb{R}^{p,q})$ given any flag φ . The type of cell determined by the Schubert symbol σ and the flag φ is given by the following proposition. Here, $\underline{\sigma}_i = \{1, \dots, \sigma_i\}$ and $\sigma(i) = \{\sigma_1, \dots, \sigma_i\}$.

Proposition 4.1. *Let $\sigma = (\sigma_1, \dots, \sigma_n)$ be a Schubert symbol and $\varphi = (\varphi_1, \dots, \varphi_q)$ be a flag symbol for $\mathbb{R}^{p,q}$. The cell $e(\sigma, \varphi)$ of $G_n(\mathbb{R}^{p,q})$ is of dimension (a, b) where $a = \sum_{i=1}^n (\sigma_i - i)$ and $b = \sum_{\sigma_i \in \varphi} |\underline{\sigma}_i \setminus (\varphi \cup \sigma(i))| + \sum_{\sigma_i \notin \varphi} |(\underline{\sigma}_i \cap \varphi) \setminus \sigma(i)|$.*

Proof. The formula for a is exactly the same as in the nonequivariant case. The one for b follows since the number of twisted coordinates in each row is exactly the number of $*$ coordinates for which the action is opposite to that on the coordinate containing the 1 in that echelon row. \square

Corollary 4.2. *The Grassmann manifolds $G_n(\mathbb{R}^{p,q})$ have free $RO(\mathbb{Z}/2)$ -graded cohomology with $\mathbb{Z}/2$ coefficients.*

Proposition 4.3. *If $V \subseteq V'$ is an inclusion of representations and $\varphi \subseteq \varphi'$ is an extension of flag symbols for V and V' , then there is a cellular inclusion $G_n(V) \hookrightarrow G_n(V')$.*

Theorem 4.4. *$H^{*,*}(G_n(\mathbb{R}^{u,v}))$ is a free $H^{*,*}(pt)$ -module with generators in bijective correspondence with the Schubert cells.*

Proof. Since $G_n(\mathbb{R}^{u,v})$ has a $Rep(\mathbb{Z}/2)$ -complex structure, we know $H^{*,*}(G_n(\mathbb{R}^{u,v}))$ is free by the freeness theorem, Theorem 3.4. Let $\{\omega_1, \dots, \omega_k\}$ be a set of free generators. Then $k \leq m$ where m is the number of Schubert cells.

These spaces are based, so we can appeal to the forgetful long exact sequence Lemma 2.1. By freeness and finite dimensionality, the multiplication by ρ map is an injection for large enough q . Thus the forgetful map to singular cohomology is surjective. Since $H_{sing}^*(G_n(\mathbb{R}^{u,v}))$ is free with generators a_1, \dots, a_m in bijective correspondence with the Schubert cells, $H^{*,*}(G_n(\mathbb{R}^{u,v}))$ has a set of elements, $\{\alpha_1, \dots, \alpha_m\}$, with $\psi(\alpha_i) = a_i$. We can uniquely express each α_i as $\alpha_i = \sum_{j=1}^k \rho^{e_{ij}} \tau^{f_{ij}} \omega_j$. We can ignore any terms that have ρ in them since $\psi(\rho) = 0$. This gives a new set of elements, $\bar{\alpha}_i = \sum_{j=1}^k \epsilon_{ij} \tau^{f_{ij}} \omega_j$, where $\epsilon_{ij} = 0$ or 1 and $\psi(\bar{\alpha}_i) = a_i$. Since $\psi(\tau) = 1$, we have that $\sum_{j=1}^k \epsilon_{ij} \psi(\omega_j) = a_i$. Since linear combinations of the linearly independent ω_j 's map to the linearly independent a_i 's, there are at least as many ω_j 's as there are a_i 's. That is, $k \geq m$. \square

The above theorem is enough to determine the additive structure of the $RO(\mathbb{Z}/2)$ -graded cohomology of the real projective spaces.

Recall that $\mathcal{U} = (\mathbb{R}^{2,1})^\infty$ is a complete universe in the sense of [May96]. Denote by $\mathbb{RP}_{tw}^\infty = \mathbb{P}(\mathcal{U})$, the space of lines in the complete universe \mathcal{U} .

Denote by $\mathbb{RP}_{tw}^n = \mathbb{P}(\mathbb{R}^{n+1}, \lfloor \frac{n+1}{2} \rfloor)$, the equivariant space of lines in $\mathbb{R}^{n+1}, \lfloor \frac{n+1}{2} \rfloor$. For example, $\mathbb{RP}_{tw}^3 = \mathbb{P}(\mathbb{R}^{4,2})$, $\mathbb{RP}_{tw}^4 = \mathbb{P}(\mathbb{R}^{5,2})$, and $\mathbb{RP}_{tw}^1 = S^{1,1}$. There are natural cellular inclusions $\mathbb{RP}_{tw}^n \hookrightarrow \mathbb{RP}_{tw}^{n+1}$, the colimit of which is \mathbb{RP}_{tw}^∞ .

Lemma 4.5. \mathbb{RP}_{tw}^n has a $\text{Rep}(\mathbb{Z}/2)$ -structure with cells in dimension $(0, 0), (1, 1), (2, 1), (3, 2), (4, 2), \dots, (n, \lceil \frac{n}{2} \rceil)$.

Proof. This follows from Proposition 4.1 using the flag symbol $\varphi = (2, 4, 6, \dots)$. \square

Lemma 4.6. \mathbb{RP}_{tw}^∞ has a cell structure with a single cell in dimension $(n, \lceil \frac{n}{2} \rceil)$, for all $n \in \mathbb{N}$.

Proof. The inclusions $\mathbb{RP}_{tw}^1 \hookrightarrow \mathbb{RP}_{tw}^2 \hookrightarrow \dots$ are cellular and their colimit is \mathbb{RP}_{tw}^∞ . \square

Proposition 4.7. As a $H^{*,*}(pt)$ -module, $H^{*,*}(\mathbb{RP}_{tw}^n)$ is free with a single generator in each bidegree $(k, \lceil \frac{k}{2} \rceil)$ for $k = 0, 1, \dots, n$.

Proof. Any nonzero differentials in the cellular spectral sequence associated to the cell structure using the flag symbol $\varphi = (2, 4, 6, \dots)$ would decrease the number of cohomology generators below the number of cells. (See Figures 9 and 10.) By Theorem 4.4 this is not the case, and so the cohomology generators have bidegrees matching the dimensions of the cells. \square

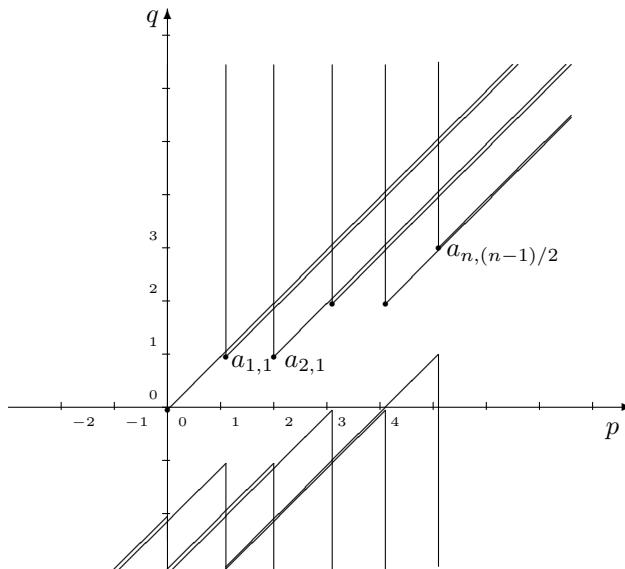

FIGURE 9. The E_1 page of the cellular spectral sequence for \mathbb{RP}_{tw}^n for n odd.

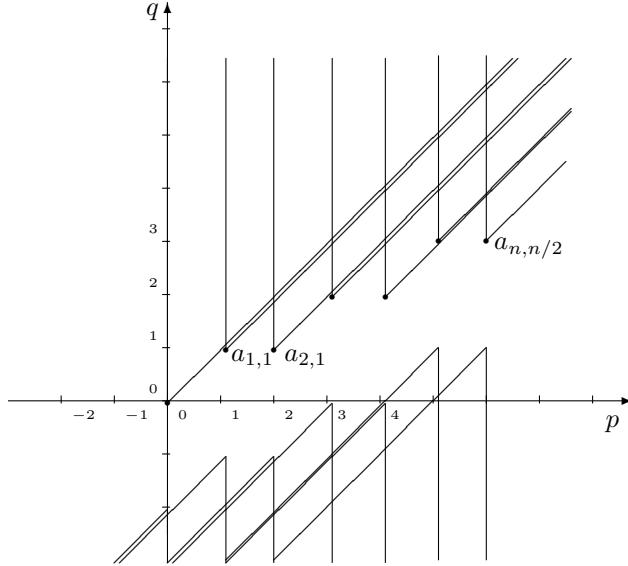

FIGURE 10. The E_1 page of the cellular spectral sequence for $\mathbb{R}\mathbb{P}_{tw}^n$ for n even.

Proposition 4.8. *As a $H^{*,*}(pt)$ -module, $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$ is free with a single generator in each bidegree $(n, \lceil \frac{n}{2} \rceil)$, for all $n \in \mathbb{N}$.*

Proof. $\mathbb{R}\mathbb{P}_{tw}^\infty$ is the colimit of the above projective spaces. Thus, any non-zero differential for $\mathbb{R}\mathbb{P}_{tw}^\infty$ would induce a non-zero differential at some finite stage. By the above proposition, this is not the case. \square

Lemma 4.9. *As a $H^{*,*}(pt)$ -module, $H^{*,*}(S^{1,1})$ is free with a single generator a in bidegree $(1, 1)$. As a ring, $H^{*,*}(S^{1,1}) \cong H^{*,*}(pt)[a]/(a^2 = \rho a)$.*

Proof. The statement about the module structure is immediate since $S^{1,1} \cong \mathbb{R}\mathbb{P}_{tw}^1$.

Since $S^{1,1}$ is a $K(\mathbb{Z}(1), 1)$, we can consider $a \in [S^{1,1}, S^{1,1}]$ as the class of the identity and $\rho \in [pt, S^{1,1}]$ as the inclusion. Then a^2 is the composite

$$a^2: S^{1,1} \xrightarrow{\Delta} S^{1,1} \wedge S^{1,1} \xrightarrow{a \wedge a} S^{2,2} \longrightarrow K(\mathbb{Z}/2(2), 2).$$

Similarly, ρa is the composite

$$\rho a: S^{1,1} \longrightarrow S^{0,0} \wedge S^{1,1} \xrightarrow{\rho \wedge a} S^{2,2} \longrightarrow K(\mathbb{Z}/2(2), 2).$$

The claim is that these two maps are homotopic. Considering the spheres involved as one point compactifications of the corresponding representations, the map a^2 is inclusion of $(\mathbb{R}^{1,1})^+$ as the diagonal in $(\mathbb{R}^{2,2})^+$ and ρa is inclusion of $(\mathbb{R}^{1,1})^+$ as the vertical axis. There is then an equivariant homotopy $H: (\mathbb{R}^{1,1})^+ \times I \rightarrow (\mathbb{R}^{2,2})^+$ between these two maps given by $H(x, t) = (tx, x)$. \square

From here, we are poised to compute the ring structure of the $RO(\mathbb{Z}/2)$ -graded cohomology of each real projective space.

Theorem 4.10. $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty) = H^{*,*}(pt)[a, b]/(a^2 = \rho a + \tau b)$, where $\deg(a) = (1, 1)$ and $\deg(b) = (2, 1)$.

Proof. It remains to compute the multiplicative structure of the cohomology ring. Denote by $a = a_{(1,1)}$, and $b = a_{(2,1)}$. By Lemma 2.1, the forgetful map $\psi: H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty) \rightarrow H_{sing}^*(\mathbb{R}\mathbb{P}^\infty)$ maps $\psi(a) = z$ and $\psi(b) = z^2$ where $z \in H_{sing}^1(\mathbb{R}\mathbb{P}^\infty)$ is the ring generator for singular cohomology. Since ψ is a homomorphism of rings, $\psi(ab) = z^3 \neq 0$, and so the product ab is nonzero in $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$. Observe that ρb is also in bidegree $(3, 2)$ in $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$, but $\psi(\rho b) = 0$ since $\psi(\rho) = 0$. Thus ab and ρb generate $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$ in bidegree $(3, 2)$. Also, $\psi(b^2) = z^4$, and so b^2 is nonzero in $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$. This means that b^2 is the unique nonzero element of $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$ in bidegree $(4, 2)$. Inductively, it can be shown that if n is even the unique nonzero element of R in bidegree $(n, \frac{n}{2})$ is $b^{n/2}$ and that if n is odd, then $ab^{(n-1)/2}$ is linearly independent from $\rho b^{(n-1)/2}$.

Now, $a^2 \in H^{2,2}(\mathbb{R}\mathbb{P}_{tw}^\infty)$ and so is a linear combination of ρa and τb . Since $\psi(a^2) = z^2$, there must be a τb term in the expression for a^2 . Also, upon restriction to $\mathbb{R}\mathbb{P}_{tw}^1 = S^{1,1}$, a^2 restricts to $a^2 = \rho a$. Thus, $a^2 = \rho a + \tau b \in H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$. \square

Theorem 4.11. Let $n > 2$. If n is even, then $H^{*,*}(\mathbb{P}(\mathbb{R}^{n, \frac{n}{2}})) = H^{*,*}(pt)[a_{1,1}, b_{2,1}]/\sim$ where the generating relations are $a^2 = \rho a + \tau b$ and $b^k = 0$ for $k \geq \frac{n}{2}$. If n is odd, then $H^{*,*}(\mathbb{P}(\mathbb{R}^{n, \frac{n-1}{2}})) = H^{*,*}(pt)[a_{1,1}, b_{2,1}]/\sim$ where the generating relations are $a^2 = \rho a + \tau b$, $b^k = 0$ for $k \geq \frac{n+1}{2}$, and $a \cdot b^{(n-1)/2} = 0$.

Proof. Only the multiplicative structure needs to be checked since the cohomology is free and the generators given above are in the correct bidegrees. Considering the restriction of the corresponding classes a and b in $H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$, the relation $a^2 = \rho a + \tau b$ is immediate. The relations $b^k = 0$ for $k > \frac{n}{2}$ when n is even and $b^k = 0$ for $k \geq \frac{n+1}{2}$ when n is odd follow for degree reasons. Also, since the class $ab^{(n-1)/2} \in H^{*,*}(\mathbb{R}\mathbb{P}_{tw}^\infty)$ is a free generator, it restricts to zero in $H^{*,*}(\mathbb{P}(\mathbb{R}^{n, \frac{n-1}{2}}))$. Thus $ab^{(n-1)/2} = 0 \in H^{*,*}(\mathbb{P}(\mathbb{R}^{n, \frac{n-1}{2}}))$. \square

We can also compute the cohomology of projective spaces associated to arbitrary representations. The following easy lemma will be useful. In particular, it allows us to only consider the projective spaces associated to representations $V \cong \mathbb{R}^{p,q}$ where $q \leq p/2$.

Lemma 4.12. $\mathbb{P}(\mathbb{R}^{p,q}) \cong \mathbb{P}(\mathbb{R}^{p,p-q})$.

Proof. Consider a basis of $\mathbb{R}^{p,q}$ in which the first q coordinates have the nontrivial action, and a basis of $\mathbb{R}^{p,p-q}$ in which the first q coordinates are fixed by the action. Then the map $f: \mathbb{P}(\mathbb{R}^{p,q}) \rightarrow \mathbb{P}(\mathbb{R}^{p,p-q})$ that sends the span of (x_1, \dots, x_p) to the span of (x_1, \dots, x_p) is equivariant. It is clearly a homeomorphism. \square

Lemma 4.13. If $q \leq p/2$, then $\mathbb{P}(\mathbb{R}^{p,q})$ has a cell structure with a single cell in each dimension $(0, 0), (1, 1), (2, 1), (3, 2), (4, 2), \dots, (2q-1, q), (2q, q), \dots, (p-1, q)$.

For example, $\mathbb{P}(\mathbb{R}^{4,1})$ has a single cell in each dimension $(0, 0), (1, 1), (2, 1)$, and $(3, 1)$.

Proof. The result follows by Proposition 4.1 using the flag symbol $\varphi = (2, 4, \dots, 2q)$. \square

Lemma 4.14. As a $H^{*,*}(pt)$ -module, $H^{*,*}(\mathbb{P}(\mathbb{R}^{p,q}))$ is free with a single generator in each bidegree $(0,0), (1,1), (2,1), (3,2), (4,2), \dots, (2q,q), (2q+1,q), \dots, (p-1,q)$.

Proof. Using the cell structure in the previous lemma, Theorem 4.4 implies there can be no nonzero differentials in the cellular spectral sequence. \square

The ring structure of the other projective spaces can be computed by considering the restriction of $H^{*,*}(\mathbb{RP}_{tw}^\infty)$ to $H^{*,*}(\mathbb{P}(\mathbb{R}^{p,q}))$.

Proposition 4.15. $H^{*,*}(\mathbb{P}(\mathbb{R}^{p,q}))$ is a truncated polynomial algebra over $H^{*,*}(pt)$ on generators in bidegrees $(1,1), (2,1), (2q+1,q), (2q+2,q), \dots, (p-1,q)$, subject to the relations determined by the restriction of

$$H^{*,*}(\mathbb{RP}_{tw}^\infty) \text{ to } H^{*,*}(\mathbb{P}(\mathbb{R}^{p,q})).$$

For example, consider $\mathbb{P}(\mathbb{R}^{4,1})$. By the above proposition, $H^{*,*}(\mathbb{P}(\mathbb{R}^{4,1}))$ is generated by classes $a_{1,1}, b_{2,1}$, and $c_{3,1}$. The classes a and b in $H^{*,*}(\mathbb{RP}_{tw}^\infty)$ restrict to a and b respectively, so $a^2 = \rho a + \tau b$ in $H^{*,*}(\mathbb{P}(\mathbb{R}^{4,1}))$. Now, ab has bidegree $(3,2)$ and so $ab = ?\rho b + ?\tau c$. However, the product ab in $H^{*,*}(\mathbb{RP}_{tw}^\infty)$ restricts to the class τc . Since restriction is a map of rings, $ab = \tau c$ in $H^{*,*}(\mathbb{P}(\mathbb{R}^{4,1}))$. Similar considerations show that $bc = 0$ and $c^2 = 0$. Thus $H^{*,*}(\mathbb{P}(\mathbb{R}^{4,1})) = H^{*,*}(pt)[a_{1,1}, b_{2,1}, c_{3,1}] / \sim$, where the generating relations are $a^2 = \rho a + \tau b$, $ab = \tau c$, $bc = 0$, and $c^2 = 0$.

In some cases, the Freedom Theorem is enough to determine the additive structure of the $RO(\mathbb{Z}/2)$ -graded cohomology of Grassmann manifolds.

Proposition 4.16. $G_2(\mathbb{R}^{p,1})$ has a $Rep(\mathbb{Z}/2)$ -complex structure so that $H^{*,*}(G_n(\mathbb{R}^{p,1}))$ is a free $H^{*,*}(pt)$ -module on generators whose bidegree match the dimensions of the cells.

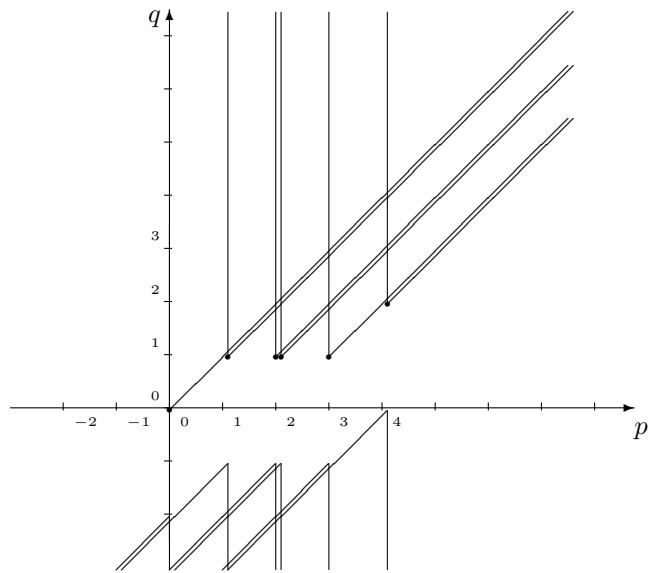

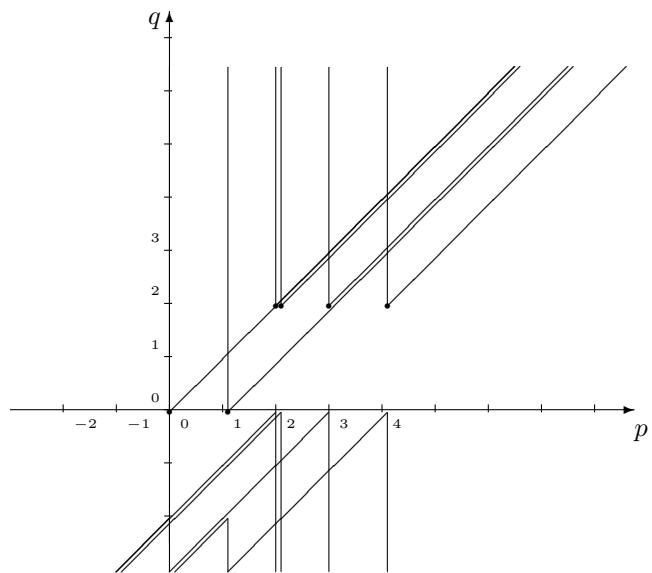

Proof. Using the flag symbol $\varphi = (2)$, every cell, except the $(0,0)$ -cell, has either one or two twists. The cells are in bidegrees so that there can be no dimension shifting in the cellular spectral sequence. The result now follows by Theorem 4.4. \square

For example, $H^{*,*}(G_2(\mathbb{R}^{4,1}); \mathbb{Z}/2)$ is a free $H^{*,*}(pt; \mathbb{Z}/2)$ -module with generators in bidegrees $(0,0), (1,1), (2,1), (2,1), (3,1)$, and $(4,2)$ (see Figure 11).

Interestingly, there are situations where there must be nonzero differentials in the cellular spectral sequences.

As another example, consider now $X = G_2(\mathbb{R}^{4,2})$. Consider the three flag symbols $\varphi_1 = (2,3)$, $\varphi_2 = (2,4)$, and $\varphi_3 = (3,4)$. The spectral sequences associated to the cell structures with these flag symbols have E_1 term given in Figures 12, 13, and 14 respectively.

The cohomology of X can be deduced by comparing these three cellular spectral sequences. We can see from the picture for φ_2 that $H^{1,0}(X) = 0$, and so the differential leaving the $(1,0)$ generator in the φ_1 spectral sequence is non-zero. Thus, $H^{1,1}(X) = \mathbb{Z}/2$, $H^{2,1}(X) = \mathbb{Z}/2$ and $H^{2,0}(X) = \mathbb{Z}/2$. In particular, there is a free generator in bidegree $(1,1)$ and there is a nontrivial differential leaving the $(2,1)$ generators of the spectral sequence for φ_2 . After a change of basis, if necessary, the differential can be adjusted so that it is zero on one of the $(2,1)$ generators and the other generator maps nontrivially. Now from φ_1 we see that $H^{4,1}(X) = 0$, and so there is a nontrivial differential leaving the $(3,1)$ generator in the φ_3 spectral

FIGURE 11. $H^{*,*}(G_2(\mathbb{R}^{4,1}))$ FIGURE 12. The E_1 page of the cellular spectral sequence for $G_2(\mathbb{R}^{4,2})$ using $\varphi_1 = (2, 3)$.

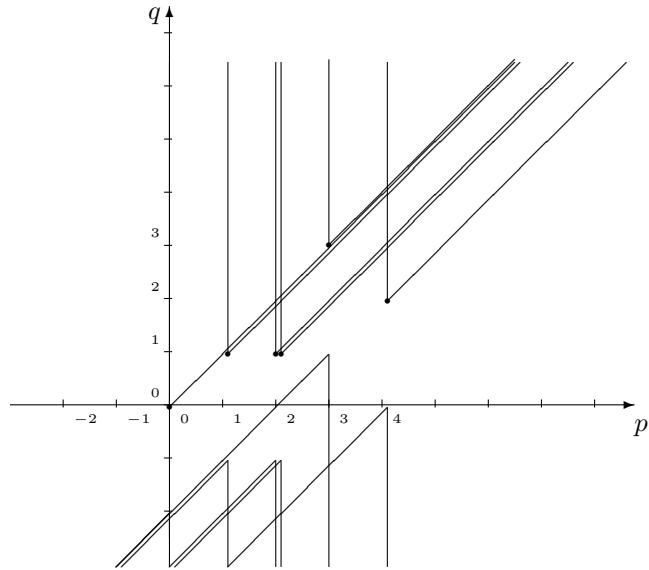

FIGURE 13. The E_1 page of the cellular spectral sequence for $G_2(\mathbb{R}^{4,2})$ using $\varphi_2 = (2, 4)$.

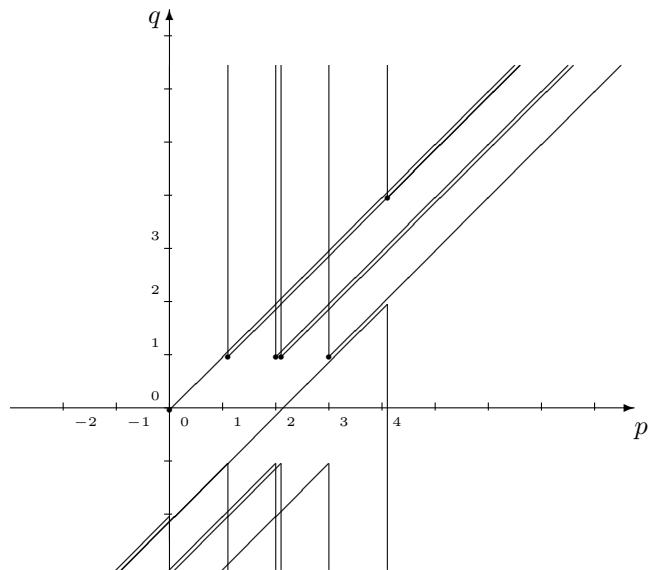

FIGURE 14. The E_1 page of the cellular spectral sequence for $G_2(\mathbb{R}^{4,2})$ using $\varphi_3 = (3, 4)$.

sequence. This means that the $(4, 2)$ generator in the φ_1 and φ_2 spectral sequences must survive. Thus, all differentials in the φ_2 spectral sequence are known. They are all zero, except for the one leaving the two $(2, 1)$ generators, which behaves as described above. That spectral sequence collapses almost immediately to give the cohomology of $G_2(\mathbb{R}^{4,2})$ pictured in Figure 15.

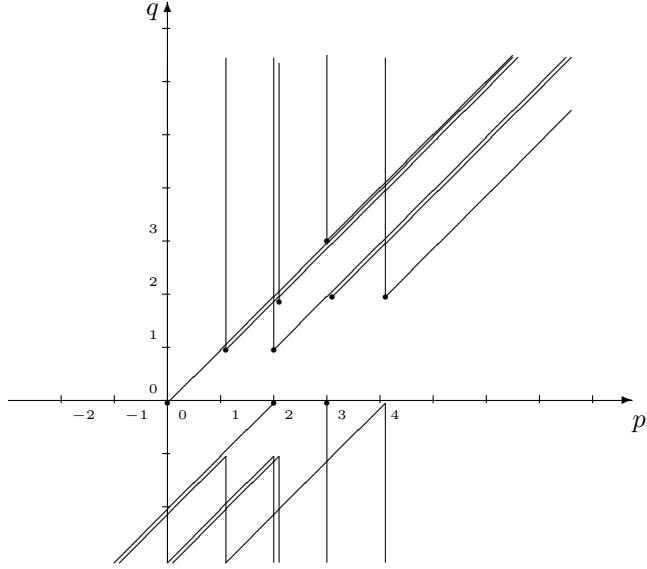

FIGURE 15. $H^{*,*}(G_2(\mathbb{R}^{4,2}))$

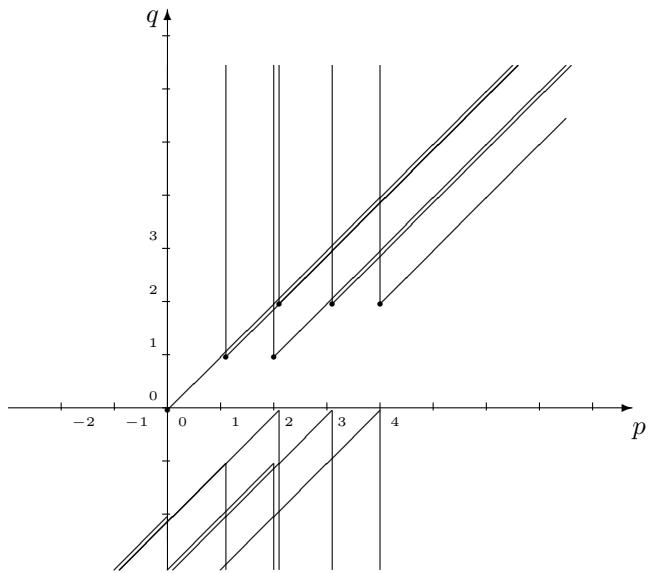

By the Freeness Theorem 3.4, we know that $H^{*,*}(G_2(\mathbb{R}^{4,2}))$ is free. Counting the $\mathbb{Z}/2$ vector space dimensions in each bidegree reveals that the dimensions are the same as those of a free $H^{*,*}(pt)$ -module with generators in bidegrees $(1, 1)$, $(2, 1)$, $(2, 2)$, $(3, 2)$, and $(4, 2)$. This is the only free $H^{*,*}(pt)$ -module with these $\mathbb{Z}/2$ dimensions, and so we have the following computation.

Proposition 4.17. $H^{*,*}(G_2(\mathbb{R}^{4,2}))$ is a free $H^{*,*}(pt)$ -module with generators in bidegrees $(1, 1)$, $(2, 1)$, $(2, 2)$, $(3, 2)$, and $(4, 2)$.

That is, $H^{*,*}(G_2(\mathbb{R}^{4,2}))$ has free generators as displayed in Figure 16.

It should be noted that in the case of $G_2(\mathbb{R}^{4,1})$, with the proper choice of flag symbols, the cell structure is such that the differentials are all zero, and so the cohomology is free with generators in the same bidegrees as the dimensions of the cells. This is **not** the case with $G_2(\mathbb{R}^{4,2})$. Regardless of the choice of flag symbol, there are some nonzero differentials which cause some degree shifting of the cohomology generators.

Unfortunately, we cannot play this game indefinitely. For the Grassmann manifolds $G_n(\mathbb{R}^{p,q})$ with n and q small enough, say $n \leq 2$ and $q \leq 2$, the above techniques can be used to obtain the additive structure of $H^{*,*}(G_n(\mathbb{R}^{p,q}))$. However, there are examples where the bidegrees of the cohomology generators cannot be determined by comparing the cellular spectral sequences for various flag symbols. A serious

FIGURE 16. $H^{*,*}(G_2(\mathbb{R}^{4,2}))$ with free generators shown.

inquiry into the geometry of the attaching maps in these cell structures may reveal more information.
